

sensorArraySimulation

A spherical magnet is assumed to be used for stimulation of the sensor array. The far field of a spherical magnet can be approximately described by the magnetic field of a magnetic dipole. The magnetization of the sphere is assumed to be in y direction and the magnetic moment in rest position for 0° points in x direction. The magnet must be defined in a way that its field lines or field strengths own gradients sufficiently strong enough in the distance to the sensor array and so the rotation of the magnet generates a small scattering of the bridge outputs in the individual sensor points in the array. That all sensors in the array approximately perceive the same magnetic field gradients of the current rotation step and the sensors in the array run through approximately equal circular paths in the characterization field. This means the spherical magnet is characterized by a favorable mating of sphere radius and a certain distance in rest position in which a sufficiently high field strength takes effect. Here are neglected small necessary distances which are demanded in standard automotive applications. The focus here is on to generate simulation datasets, which are uniform and valid for angle detection. The modelling of suitable small magnets is not taking place of the work.

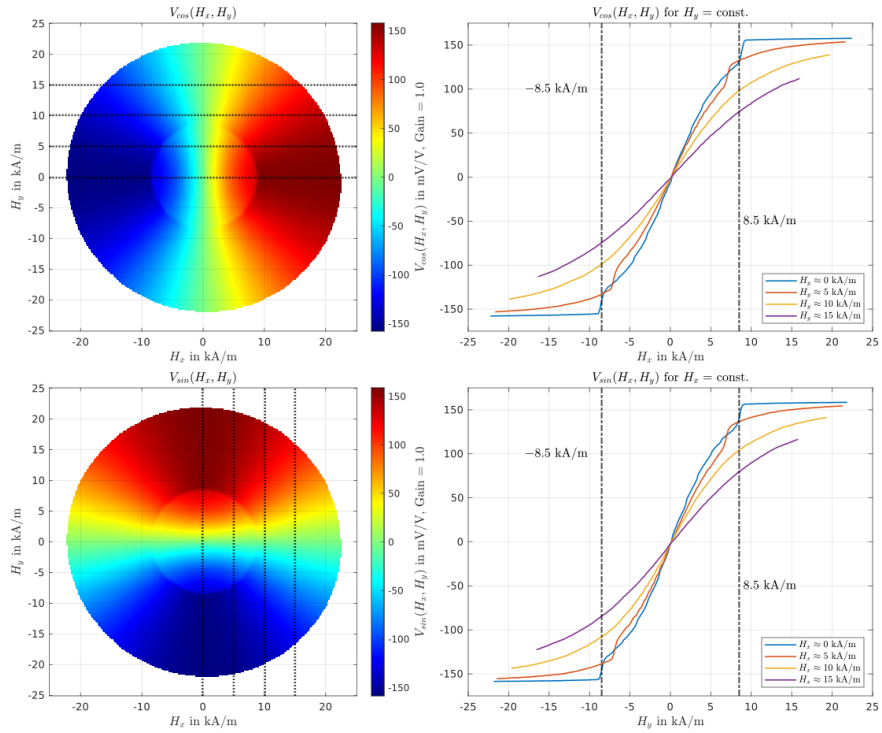

A good working magnet is found empirical for H-field magnitudes of 200 kA/m and a distance from surface of 1 mm. See below figure of used magnet.

To change settings for simulation edit the config script and rerun it. To generate training and test data set use simulation script. It generates dataset for all position are known to TrainingOptions and TestOptions in config. Generate a set of dataset for one evaluation case. Evaluate datasets, save results for later clustering, edit config for next use case and rerun simulation.

The simulation bases on TDK TAS2141 "Rise" chracterization field. It has the widest linear plateau for corresponding Hx and Hy field strengths.

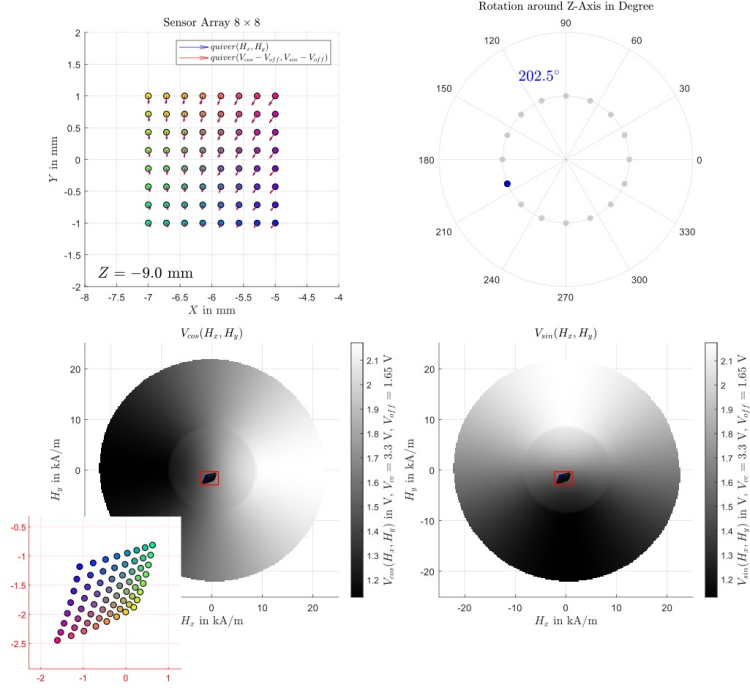

Characterization Field: Rise
 TDK TAS2141 TMR Angular Sensor Characterization Dataset.
 Created on 2019-07-24 by Thorben Schütte and updated on 2020-10-22 by Tobias Wulf.

Here are some example plots of sensor array simulation with described magnet configuration from above and TDK Rise characterization field as behavior base.

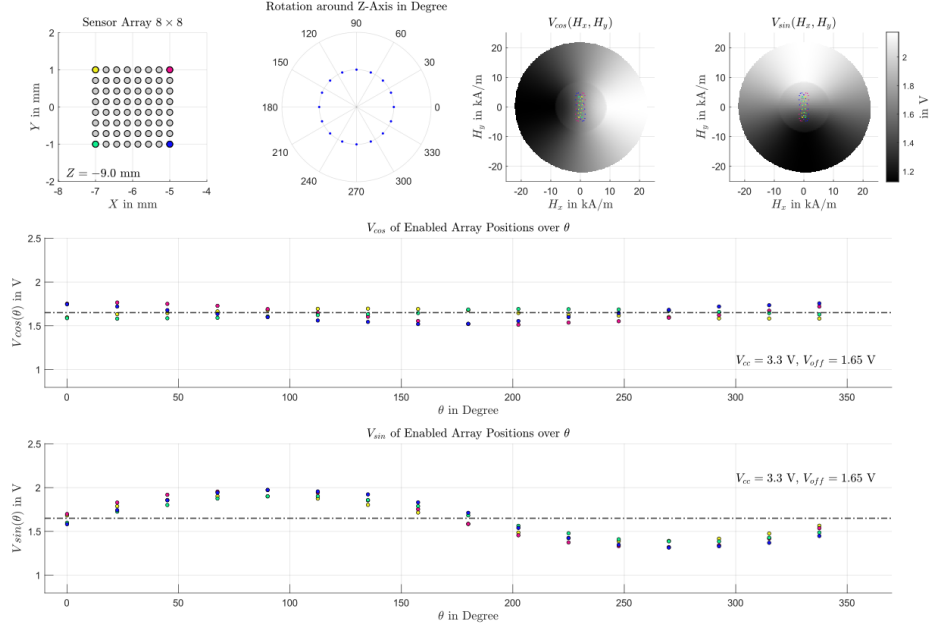

Sensor Array Simulation

Sensor Array (square) of 8×8 sensors, an edge length of 2.0 mm, a rel. pos. to magnet surface of $(-6.0, 0.0, -(7.0))$ in mm, a magnet tilt of 0.0° , a sphere radius of 2.0 mm, a imprinted field strength of 200.0 kA/m at 1.0 mm from sphere surface in z-axis, 16 rotation angles with a step width of 22.5° and a resolution of 0.5° . Visualized is rotation angle 10 (202.5°).
Based on TDK TAS2141 characterization reference Rise.

Sensor Array Simulation

Sensor Array (square) of 8×8 sensors, an edge length of 2.0 mm, a rel. pos. to magnet surface of $(-6.0, 0.0, -(7.0))$ in mm, a magnet tilt of 0.0° , a sphere radius of 2.0 mm, a imprinted field strength of 200.0 kA/m at 1.0 mm from sphere surface in z-axis, 16 rotation angles with a step width of 22.5° and a resolution of 0.5° . Visualized is a subset of 16 angles in sample distance of 1 angles. Based on TDK TAS2141 characterization reference Rise.

simulateDipoleSquareSensorArray

Simulate a square sensor array with dipole magnet as stimulus for a certain setup of training or test options. Saves generated dataset to data/training or data/test.

computeDipoleHField

Compute dipole field strength for meshgrids with additional ability to imprint a certain field strength in defined radius on

resulting field.

computeDipoleH0Norm

Compute a norm factor to imprint a magnetic field strength to magnetic dipole fields with same magnetic moment magnitude and constant dipole sphere radius on which the imprinted field strengt takes effect.

generateSensorArraySquareGrid

Generat a square sensor array grid in a 3D coordinate system with relative position to center of the system and an additional offset in z direction.

generateDipoleRotationMoments

Generate magnetic rotation moments to rotate a magnetic dipol in its z-axes with a certain tilt.

rotate3DVector

Rotate a vector with x-, y- and z-components in a 3D-coordinate system. Rotate one step of certain angles.
